

# SEMI-MARKOV PROCESSES FOR RELIABILITY STUDIES

CHRISTIANE COCOZZA-THIVENT AND MICHEL ROUSSIGNOL

**ABSTRACT.** We study the evolution of a multi-component system which is modeled by a semi-Markov process. We give formulas for the availability and the reliability of the system. In the  $r$ -positive case, we prove that the quasi-stationary probability on the working states is the normalised left eigenvector of some computable matrix and that the asymptotic failure rate is equal to the absolute value of the convergence parameter  $r$ .

## 1. INTRODUCTION

The motivation of this paper comes from reliability studies. We consider a system whose possible states form a finite set  $E$ . The set  $E$  is splitted into two subsets,  $\mathcal{M}$  corresponding to the working states and  $\mathcal{P}$  corresponding to the failure states. We are interested in the time evolution of the system. There is an important literature on this subject when the evolution is modeled by a Markov process (cf Pages and Gondran (1980)). However there are cases where the evolution cannot be modeled by a Markov process, but can be modeled by a semi-Markov process. In this case by standard techniques on semi-Markov processes (cf Cinlar (1975)), it is possible to obtain formulas for the availability and the reliability. Furthermore, in order to obtain a description of this evolution up to the first failure time, it is interesting to compute the quasi-stationary distribution on  $\mathcal{M}$ . The existence of quasi-stationary distributions for semi-Markov processes has been proved in Cheong (1970). The main goal of this paper is to give a method to compute this distribution in the context of reliability studies. In addition we prove that the convergence parameter is equal to the asymptotic failure rate.

In section 2 we recall classical properties of semi-Markov processes and we give a formula to compute the Laplace transform of the availability. In section 3 we define a transient semi-Markov process which allows to compute the Laplace transform of the reliability. A family  $A(s)$  of matrices appears in the formulas of availability and reliability. In the Markov case these matrices are equal to the generating matrix of the process. In section 4 we recall properties of  $r$ -recurrent and  $r$ -positive semi-Markov processes where  $r$  is the convergence parameter. If the process is  $r$ -recurrent, we prove that  $r$  is the Perron-Frobenius eigenvalue of the matrix  $A_1(r)$ , restriction to  $\mathcal{M}$  of the matrix  $A(r)$ . In section 5 we prove that when the process is  $r$ -recurrent, with additional hypotheses, the process is  $r$ -positive and that the quasi-stationary distribution on  $\mathcal{M}$  is the normalized left eigenvector of the matrix  $A_1(r)$ .

This gives a practical method to compute the quasi-stationary distribution on  $\mathcal{M}$ . We prove in section 6 that under natural hypotheses, the asymptotic failure rate of the system is equal to  $|r|$ . We give in section 7 a numerical example.

## 2. SOME PROPERTIES OF A SEMI-MARKOV PROCESS

The semi-Markov process  $(Y_t)_{t \geq 0}$  is defined by means of a random sequence  $(X_n, T_n)_{n \in \mathbb{N}}$  where  $(X_n)_{n \in \mathbb{N}}$  represents the different positions of the process and  $(T_n)_{n \in \mathbb{N}}$  the jump times. The process  $(X_n)_{n \in \mathbb{N}}$  takes its values in a finite set  $E$  and  $(T_n)_{n \in \mathbb{N}}$  is an increasing sequence of positive random variables with  $T_0 = 0$ . We have:

$$Y_t = \sum_{n \geq 0} X_n 1_{\{T_n \leq t < T_{n+1}\}}$$

The random properties of the process are characterized by the following semi-Markov property. For any Borel set  $A$  of  $\mathbb{R}_+$ , any state  $j$  in  $E$  and any  $n$  in  $\mathbb{N}$ , we have:

$$\begin{aligned} \mathbb{P}(X_{n+1} = j, T_{n+1} - T_n \in A / X_0, \dots, X_n, T_0, \dots, T_n) \\ &= \mathbb{P}(X_{n+1} = j, T_{n+1} - T_n \in A / X_n) \\ &= \int_A Q(X_n, j, du) \end{aligned}$$

where  $A \rightarrow Q(i, j, A)$  is a bounded measure on  $\mathbb{R}_+$  for all  $i$  and  $j$  in  $E$ . We shall use results on semi-Markov processes which can be found in Cinlar (1975). The process  $(X_n)_{n \geq 0}$  is a Markov chain with transition probabilities  $P(i, j) = Q(i, j, \mathbb{R}_+) = \int_{\mathbb{R}_+} Q(i, j, du)$ . Let  $f(i, du)$  be the probability law of  $T_{n+1} - T_n$  conditionally on  $\{X_n = i\}$  and  $h(i, t) = \int_{]t, +\infty[} f(i, du)$ . We have:

$$f(i, du) = \sum_{j \in E} Q(i, j, du)$$

Let  $Q_{(n)}(i, j, du)$  be the probability law of  $(X_n, T_n)$  conditionally on  $\{X_0 = i\}$ :

$$\mathbb{P}(X_n = j, T_n \in A / X_0 = i) = \int_A Q_{(n)}(i, j, du)$$

We have  $Q_{(0)}(i, j, \cdot) = I(i, j) \delta_0(\cdot)$  where  $I$  is the identity matrix on  $E \times E$  and  $\delta_0$  the Dirac measure on 0,  $Q_{(1)}(i, j, \cdot) = Q(i, j, \cdot)$ ,  $Q_{(n+1)}(i, k, \cdot) = \sum_{j \in E} Q(i, j, \cdot) * Q_{(n)}(j, k, \cdot)$ .

We define the renewal Markovian kernel by:

$$R(i, j, du) = \sum_{n \geq 0} Q_{(n)}(i, j, du).$$

We have:

$$\mathbb{P}(Y_t = j / Y_0 = i) = \int_{[0, t]} h(j, t-s) R(i, j, ds).$$

We shall deal with Laplace transforms  $Q^*(i, j, s)$ ,  $f^*(i, s)$ ,  $Q_{(n)}^*(i, j, s)$ ,  $R^*(i, j, s)$ ,  $h^*(i, s)$ ,  $P^*(i, j, s)$  respectively of measures  $Q(i, j, du)$ ,  $f(i, du)$ ,  $Q_{(n)}(i, j,$

$du$ ),  $R(i, j, du)$  and of functions  $t \rightarrow h(i, t)$ ,  $t \rightarrow \mathbb{P}(Y_t = j/Y_0 = i)$ . Let  $Q^*(s)$ ,  $Q_{(n)}^*(s)$ ,  $R^*(s)$ ,  $P^*(s)$  be the associated matrices. We have:

$$Q_{(n)}^*(s) = (Q^*(s))^n$$

$$f^*(i, s) = \sum_{j \in E} Q^*(i, j, s)$$

$$s h^*(i, s) = 1 - f^*(i, s)$$

$$R^*(s) = \sum_{n \geq 0} (Q^*(s))^n$$

$$P^*(i, j, s) = R^*(i, j, s) h^*(j, s)$$

Since the measures  $Q(i, j, du)$  are bounded, the Laplace transforms  $Q^*(i, j, s)$ ,  $Q_{(n)}^*(i, j, s)$  and  $f^*(i, s)$  are finite for  $s$  non negative.

We get the following result.

PROPOSITION 2.1. *Let us define the matrix  $A(s)$  on  $E \times E$  by*

$$A(i, j, s) = \frac{Q^*(i, j, s)}{h^*(i, s)} \text{ if } i \neq j$$

$$A(i, i, s) = - \sum_{\{j:j \neq i\}} \frac{Q^*(i, j, s)}{h^*(i, s)}$$

*If  $s$  is strictly positive, the Laplace transform of the transition probabilities matrix is given by:*

$$P^*(s) = (sI - A(s))^{-1}$$

*Proof.* We know that:  $P^*(k, j, s) = R^*(k, j, s)h^*(j, s)$ . Replacing  $R^*(k, j, s)$  by  $\frac{P^*(k, j, s)}{h^*(j, s)}$  in the equation  $R^* = I + R^*Q^*$  gives:

$$\frac{P^*(i, j, s)}{h^*(j, s)} = I(i, j) + \sum_{k \in E} \frac{P^*(i, k, s)}{h^*(k, s)} Q^*(k, j, s)$$

The relation  $h^*(i, s) = \frac{1-f^*(i, s)}{s}$  can be written:

$$\frac{1}{h^*(j, s)} = s + \frac{f^*(j, s)}{h^*(j, s)} = s + \sum_{k \in E} \frac{Q^*(j, k, s)}{h^*(j, s)}$$

So we get:

$$sP^*(i, j, s) + P^*(i, j, s) \sum_{k \in E} \frac{Q^*(j, k, s)}{h^*(j, s)} = I(i, j) + \sum_{k \in E} P^*(i, k, s) \frac{Q^*(k, j, s)}{h^*(k, s)}$$

This relation is equivalent to:  $P^*(s)(sI - A(s)) = I$  which is the desired result. □

In the Markovian case, the matrices  $A(s)$  are constant and equal to the generating matrix of the Markov process. The formula above is a generalisation of a well-known formula in the Markovian case.

### 3. THE TRANSIENT PROCESS

To compute the reliability of the system, we define a new semi-Markov process  $(Z_t)_{t \geq 0}$  which behaves exactly like the process  $(Y_t)_{t \geq 0}$  until the first failure time. However, when the process reaches a failure state, it stays in failure states forever. Let  $\tilde{Q}(i, j, du)$  be the measures defining this new process, then we get:

- for  $i$  in  $\mathcal{M}$  :  $\tilde{Q}(i, j, du) = Q(i, j, du)$
- for  $i$  in  $\mathcal{P}$  and  $j$  in  $\mathcal{M}$ :  $\tilde{Q}(i, j, du) = 0$
- for  $i$  in  $\mathcal{P}$  and  $j$  in  $\mathcal{P}$ :  $\tilde{Q}(i, j, du) = \text{anything}$ .

Of course the new process is not irreducible in  $E$ .

*From now on, we suppose that  $\mathcal{M}$  is a transient irreducible set for the process  $(Z_t)_{t \geq 0}$ .*

We denote by “tilde” letters the quantities related to the process  $(Z_t)_{t \geq 0}$ . Let  $Q_1^*(s)$  and  $R_1^*(s)$  be the restrictions of the matrices  $\tilde{Q}^*(s)$  and  $\tilde{R}^*(s)$  to  $\mathcal{M} \times \mathcal{M}$

It is easy to check that

$$\forall i, j \in \mathcal{M} : \tilde{A}(i, j, s) = A(i, j, s), (\tilde{Q}^*(s))^n(i, j) = (Q_1^*(s))^n(i, j),$$

$$R_1^*(s) = \sum_{n \geq 0} (Q_1^*(s))^n, \quad R_1^*(s) = I_1 + R_1^*(s)Q_1^*(s), \quad (3.1)$$

where  $I_1$  is the identity matrix on  $\mathcal{M} \times \mathcal{M}$ .

#### 3.1. SOME DEFINITIONS

Let  $\tilde{r}(i, j)$  be the convergence abscissa of the Laplace transform  $Q_1^*(i, j, s)$  and

$$\tilde{r} = \sup_{i, j} \tilde{r}(i, j).$$

REMARK 3.1. If there exist  $i$  and  $j$  (in  $\mathcal{M}$ ) such that  $Q_1^*(i, j, \tilde{r}) = +\infty$ , we shall say that we are in the usual case. The reason for this terminology is that this is the case for measures with rational Laplace transforms.

It was shown in Cheong (1968) that all the convergence abscissas of the Laplace transforms  $R_1^*(i, j, s)$  are equal (since the set  $\mathcal{M}$  is irreducible). We denote this number by  $r$ .

DEFINITION 3.2. The common convergence abscissa of the Laplace transforms  $R_1^*(i, j, s)$  is called the convergence parameter.

We get:

$$\tilde{r} \leq r \leq 0.$$

Let  $\rho(s)$  be the Perron-Frobenius eigenvalue of  $\tilde{Q}_1^*(s)$ . This function enables us to compute  $r$ .

REMARK 3.3.

1. The function  $s \rightarrow \rho(s)$  is decreasing (Seneta (1973)) and continuous (since the coefficients of the matrix  $Q_1^*(s)$  are continuous) on the interval  $]\tilde{r}, +\infty[$ .

2. If  $\rho(0)$  exists, then, since  $\mathcal{M}$  is a transient irreducible set, the Perron Frobenius theorem gives  $\rho(0) < 1$ .
3. If  $\rho(s)$  tends to a limit strictly greater than 1 as  $s$  decreases to  $\tilde{r}$  (which is true in the usual case - see remark 3.1 -) and if  $\rho(0) < 1$  then the greatest value  $s$  such that  $\rho(s) = 1$  is the convergence parameter  $r$  by formula (3.1).

### 3.2. RELIABILITY

In order to compute the reliability of the system, we must compute the transition probabilities of the new process.

PROPOSITION 3.4. *Suppose that for  $s > r$ ,  $Q^*(i, j, s) < \infty$  for all  $i$  in  $\mathcal{M}$  and  $j$  in  $\mathcal{P}$ . If  $A_1(s)$  is the restriction of the matrix  $A(s)$  to  $\mathcal{M} \times \mathcal{M}$ , then we have:*

$$\forall s > r, \tilde{P}_1^*(s) = (sI_1 - A_1(s))^{-1}$$

where  $\tilde{P}_1^*(s)$  is the restriction to  $\mathcal{M} \times \mathcal{M}$  of the Laplace transforms matrix of the transition probabilities for the new process.

*Proof.* For  $s > r$  we have  $f^*(i, s) < \infty$ . It is easy to check that  $f^*(i, s) < \infty$  implies  $h^*(i, s) < \infty$ . Hence we can prove proposition 3.4 in the same way as proposition 2.1. □

REMARK 3.5. Note that if  $Q(i, j, du) = P(i, j)f(i, du)$ , then for  $s > r$ ,  $f^*(i, s) < \infty$  for all  $i$  in  $\mathcal{M}$ , and  $Q^*(i, j, s) < \infty$  for every  $j$ . So the assumption in the above proposition is satisfied.

Proposition 3.4 enables us to calculate the Laplace transform  $RE^*(i, s)$  of the reliability for the initial process starting from the working state  $i$  and the associated mean time to failure  $MTTF(i)$ . Given that  $RE(i, t) = \sum_{j \in \mathcal{M}} \mathbb{P}(Z_t = j / Z_0 = i)$  and  $MTTF(i) = RE^*(i, 0)$ , we get:

$$RE^*(i) = \sum_{j \in \mathcal{M}} (sI_1 - A_1(s))^{-1}(i, j)$$

$$MTTF(i) = - \sum_{j \in \mathcal{M}} (A_1(0))^{-1}(i, j)$$

For  $i \neq j$ ,  $A_1(i, j, 0) = P(i, j) / \mathbb{E}(T_1 / Y_0 = i)$  and  $A_1(i, i, 0) = (P(i, i) - 1) / \mathbb{E}(T_1 / Y_0 = i)$ . This proves the following result: since the  $MTTF$  depends only on the embedded markov chain  $(X_n)_{n \geq 0}$  and the mean sojourn time in the states, it is equal to the mean time to failure of a Markov process with the same transition probabilities  $P(i, j)$  and the same mean sojourn time in each state.

### 4. THE R-RECURRENCE PROPERTY

Before introducing  $r$ -recurrence, we need some material.

For any state  $j$ , let  $\tilde{F}(j, j, \cdot)$  be the law of the first return time to  $j$  of the process  $(Z_t)_{t \geq 0}$  starting from  $j$ ; for any state  $i$  different from  $j$ , let  $\tilde{F}(i, j, \cdot)$  be the law of the first visit time to  $j$  of the process  $(Z_t)_{t \geq 0}$  starting from  $i$ . These laws are defined on  $\mathbb{R}_+ \cup +\infty$ . Because the process is irreducible and transient on  $\mathcal{M}$ , the quantities  $\tilde{F}(j, j, \mathbb{R}_+)$  are strictly less than 1 for  $j$  in  $\mathcal{M}$ . If  $i$  is in  $\mathcal{P}$  and  $j$  in  $\mathcal{M}$ ,  $\tilde{F}(i, j, \mathbb{R}_+)$  equals 0. Let  $\tilde{F}^*(i, j, s)$  be the

Laplace transform of  $\tilde{F}(i, j, \cdot)$ . Given that  $\tilde{R}^*(i, j, s) = \tilde{F}^*(i, j, s)\tilde{R}^*(j, j, s)$  for  $i \neq j$  and  $\tilde{R}^*(j, j, s) = \sum_{n \geq 0} (\tilde{F}^*(j, j, s))^n$  (cf Cinlar (1975) 10.2.12 and 10.2.13), then for  $s > r$  and  $j$  in  $\mathcal{M}$  we have:

$$\begin{aligned} \tilde{F}^*(j, j, s) &< 1 \\ \tilde{R}^*(j, j, s) &= \frac{1}{1 - \tilde{F}^*(j, j, s)} \\ \tilde{R}^*(i, j, s) &= \frac{\tilde{F}^*(i, j, s)}{1 - \tilde{F}^*(j, j, s)} \text{ if } i \neq j \end{aligned}$$

REMARK 4.1.

If  $\lim_{s \searrow r} \tilde{R}^*(j, j, s) = +\infty$ , then  $\lim_{s \searrow r} \tilde{F}^*(j, j, s) = \tilde{F}^*(j, j, r) = 1$ .

If  $\lim_{s \searrow r} \tilde{R}^*(j, j, s) < +\infty$ , then  $\lim_{s \searrow r} \tilde{F}^*(j, j, s) = \tilde{F}^*(j, j, r) < 1$ ; so in any case  $\tilde{F}^*(j, j, r) \leq 1$ .

LEMMA 4.2. For  $s > r$  and  $i, j$  in  $\mathcal{M}$ , we have the relations:

$$\begin{aligned} \tilde{F}^*(i, j, s) &= \sum_{k \in \mathcal{M}} \tilde{Q}^*(i, k, s) \tilde{F}^*(k, j, s) + \tilde{Q}^*(i, j, s)(1 - \tilde{F}^*(j, j, s)) \\ \tilde{F}^*(i, j, s) &= \sum_{k \in \mathcal{M}} \tilde{F}^*(i, k, s) \tilde{Q}^*(k, j, s) \frac{1 - \tilde{F}^*(j, j, s)}{1 - \tilde{F}^*(k, k, s)} \\ &\quad + \tilde{Q}^*(i, j, s)(1 - \tilde{F}^*(j, j, s)) \end{aligned}$$

*Proof.* If  $i$  is different from  $j$ , replace  $\tilde{R}^*(j, j, s)$  by  $1/(1 - \tilde{F}^*(j, j, s))$  and  $\tilde{R}^*(i, j, s)$  by  $\tilde{F}^*(i, j, s)/(1 - \tilde{F}^*(j, j, s))$  in formulas  $\tilde{R}^*(s) = I + \tilde{Q}^*(s)\tilde{R}^*(s)$  and  $\tilde{R}^*(s) = I + \tilde{R}^*(s)\tilde{Q}^*(s)$ .  $\square$

REMARK 4.3. We can deduce from the preceding lemma and the irreducibility assumption that for  $s \geq r$  and  $i, j$  in  $\mathcal{M}$ , we have:

$$\tilde{F}^*(i, j, s) < \infty \text{ and } \tilde{Q}^*(i, j, s) < \infty.$$

The notion of  $r$ -recurrence for a semi-Markov process was defined in Cheong (1968). It is known that if for at least one state  $j$  in  $\mathcal{M}$  we have

$$\lim_{s \searrow r} R_1^*(j, j, s) = R_1^*(j, j, r) = +\infty$$

then this property applies for any state  $j$  in  $\mathcal{M}$ .

DEFINITION 4.4. The process is said to be  $r$ -recurrent on  $\mathcal{M}$  if for at least one state  $j$  in  $\mathcal{M}$  we have

$$\lim_{s \searrow r} R_1^*(j, j, s) = R_1^*(j, j, r) = +\infty$$

REMARK 4.5. The equality  $R_1^*(j, j, r) = +\infty$  is equivalent to the equality  $\tilde{F}^*(j, j, r) = 1$  for  $j \in \mathcal{M}$  (cf remark 4.1).

REMARK 4.6. Note that since,  $R_1^*(j, j, r) = \sum_{n \geq 0} (Q_1^*)^n(j, j, r)$ , the condition  $R_1^*(j, j, r) = +\infty$  is equivalent to  $\rho(r) \geq 1$ .

REMARK 4.7. We have seen that in the usual case the Perron-Frobenius eigenvalue  $\rho(r)$  of  $Q_1^*(r)$  is equal to 1. In that case the process is  $r$ -recurrent.

REMARK 4.8. Since the semi-Markov process  $(Z_t)_{t \geq 0}$  is transient and irreducible on  $\mathcal{M}$ , we have for  $j$  in  $\mathcal{M}$ ,  $\tilde{F}^*(j, j, 0) < 1$ . Thus if the process is  $r$ -recurrent,  $r$  is necessarily strictly negative.

In order to find other properties of the value  $r$ , we need a technical lemma.

LEMMA 4.9. *If the process is  $r$ -recurrent we have for  $i$  and  $j$  in  $\mathcal{M}$ :*

$$\begin{aligned} \tilde{F}^*(i, j, r) &= \sum_{k \in \mathcal{M}} \tilde{Q}^*(i, k, r) \tilde{F}^*(k, j, r) \\ \frac{\tilde{F}^*(i, j, r)}{(\tilde{F}^*)'(j, j, r)} &= \sum_{k \in \mathcal{M}} \frac{\tilde{F}^*(i, k, r)}{(\tilde{F}^*)'(k, k, r)} \tilde{Q}^*(k, j, r) \end{aligned}$$

*Proof.* We let  $s$  tend to  $r$  in the first formula of lemma 4.2 and we obtain, using remark 4.1, for  $i, j$  in  $\mathcal{M}$ :

$$\tilde{F}^*(i, j, r) = \sum_{k \in \mathcal{M}} \tilde{Q}^*(i, k, r) \tilde{F}^*(k, j, r).$$

Now multiply the second formula of lemma 4.2 by  $(s - r)/(1 - \tilde{F}^*(j, j, s))$  and take the limit as  $s$  decreases to  $r$ . The limit of  $(1 - \tilde{F}^*(j, j, s))/(s - r) = (\tilde{F}^*(j, j, r) - \tilde{F}^*(j, j, s))/(s - r)$  always exists as  $s$  decreases to  $r$  and is equal to  $-(\tilde{F}^*)'(j, j, r) = \int_0^\infty x e^{-rx} \tilde{F}^*(j, j, dx)$  (use the dominated convergence theorem or Fatou's lemma). This quantity is finite or infinite. In either case we obtain the last formula.  $\square$

PROPOSITION 4.10. *If the process is  $r$ -recurrent, then  $r$  is the Perron-Frobenius eigenvalue of  $A_1(r)$ .*

*Proof.* For  $j$  and  $\ell$  in  $\mathcal{M}$  we have:

$$\begin{aligned} &\sum_{i \in \mathcal{M}} A_1(\ell, i, r) \tilde{F}^*(i, j, r) \\ &= \sum_{\{i \in \mathcal{M}/i \neq \ell\}} \frac{Q^*(\ell, i, r)}{h^*(\ell, r)} \tilde{F}^*(i, j, r) - \sum_{\{i \in E/i \neq \ell\}} \frac{Q^*(\ell, i, r)}{h^*(\ell, r)} \tilde{F}^*(\ell, j, r) \\ &= \sum_{i \in \mathcal{M}} \frac{Q^*(\ell, i, r)}{h^*(\ell, r)} \tilde{F}^*(i, j, r) - \sum_{i \in E} \frac{Q^*(\ell, i, r)}{h^*(\ell, r)} \tilde{F}^*(\ell, j, r) \end{aligned}$$

Using lemma 4.9, we obtain:

$$\begin{aligned} \sum_{i \in \mathcal{M}} A_1(\ell, i, r) \tilde{F}^*(i, j, r) &= \tilde{F}^*(\ell, j, r) \frac{1 - f^*(\ell, r)}{h^*(\ell, r)} \\ &= r \tilde{F}^*(\ell, j, r). \end{aligned}$$

Therefore  $r$  is an eigenvalue of  $A_1(r)$  associated with the positive vector  $(\tilde{F}^*(i, j, r), i \in \mathcal{M})$ . By the subinvariance theorem (cf Seneta (1973) p.23),  $r$  is the Perron-Frobenius eigenvalue of  $A_1(r)$ .  $\square$

In the following sections, we shall use the renewal theorem to prove the existence of limits. The next proposition gives the version of that theorem we shall use. We say that a finite measure is *spread out* if, for some  $n$ , its  $n$ -th convolution power has a component which has a density with respect to the Lebesgue measure (cf Asmussen (1992) p.140).

PROPOSITION 4.11. *Suppose that for any  $j$  in  $\mathcal{M}$  the measures  $\tilde{F}(j, j, du)$  are spread out and that the process is  $r$ -recurrent. If  $g$  is a positive function on  $\mathbb{R}_+$ , such that the function  $x \rightarrow e^{-rx}g(x)$  is bounded, tends to 0 as  $x$  tends to  $+\infty$  and is Lebesgue integrable, then for any  $i$  and  $j$  in  $\mathcal{M}$  we have:*

$$\lim_{t \rightarrow \infty} e^{-rt} \int_0^t g(t-s)R(i, j, ds) = \frac{g^*(r)\tilde{F}^*(i, j, r)}{-(\tilde{F}^*)'(j, j, r)}$$

(where  $g^*(s)$  is the Laplace transform of the function  $g$ ).

This theorem can be deduced from the renewal theorem given in Asmussen (1992) corollary VI.1.3.

The limit in the above theorem is strictly positive if the quantity  $(\tilde{F}^*)'(j, j, r)$  is finite. It was proved in Cheong (1968) that if for at least one  $j$  in  $\mathcal{M}$  the quantity  $(\tilde{F}^*)'(j, j, r)$  is finite, then it is finite for any  $j$  in  $\mathcal{M}$ .

DEFINITION 4.12. The process is said to be  $r$ -positive if it is  $r$ -recurrent and if

$$(\tilde{F}^*)'(j, j, r) = - \int_0^\infty x e^{-rx} \tilde{F}^*(j, j, dx)$$

is finite for any  $j$  in  $\mathcal{M}$ .

In the following proposition we consider a process which is not  $r$ -recurrent.

PROPOSITION 4.13. *Suppose that the process is not  $r$ -recurrent. If  $g$  is a positive function on  $\mathbb{R}_+$ , such that the function  $x \rightarrow e^{-rx}g(x)$  is bounded, tends to 0 as  $x$  tends to  $+\infty$  and is Lebesgue integrable, then for any  $i$  and  $j$  in  $\mathcal{M}$  we have:*

$$\lim_{t \rightarrow \infty} e^{-rt} \int_0^t g(t-s)\tilde{R}(i, j, ds) = 0$$

*Proof.* For  $i \neq j$  in  $\mathcal{M}$  we have:

$$e^{-rt} \int_0^t g(t-s)\tilde{R}_1(i, j, ds) = \int_0^t e^{-r(t-s)}(\tilde{F}(i, j, \cdot) * g(\cdot))(t-s)e^{-rs}\tilde{R}_1(j, j, ds).$$

Since the process is not  $r$ -recurrent, the measure  $e^{-rs}R_1(j, j, ds)$  is finite on  $\mathbb{R}_+$ . The function  $t \rightarrow e^{-r(t-s)}(\tilde{F}(i, j, \cdot) * g(\cdot))(t-s)$  tends to 0 as  $t$  tends to  $+\infty$  and is bounded uniformly in  $s$ . It is sufficient now to use the dominated convergence theorem.

The proof for the case  $i = j$  is similar. □

### 5. QUASI-STATIONARY PROBABILITY ON WORKING STATES

A quasi-stationary probability on  $\mathcal{M}$  is given by :

$$\lim_{t \rightarrow \infty} \frac{\mathbb{P}(Z_t = j / Z_0 = i)}{\sum_{j \in \mathcal{M}} \mathbb{P}(Z_t = j / Z_0 = i)}.$$

The existence of the quasi-stationary probability on  $\mathcal{M}$  is proved in Cheong (1970) if the process is  $r$ -positive and if the total variations in  $[0, \infty)$  of the functions  $t \rightarrow e^{-rt}h(i, t)$  are finite. In this section we first prove the existence of the quasi-stationary distribution under slightly different conditions. Our main improvement on the results of Cheong (1970) is that we are able to identify the quasi-stationary distribution as a left eigenvalue of a computable

matrix. As we are on a finite space we also prove that under our assumptions, an  $r$ -recurrent process is  $r$ -positive.

For the next theorem, we will introduce the following assumption:

$$(A_0) \begin{cases} 1) \text{ the process is } r - \text{recurrent} \\ 2) \forall j \in \mathcal{M} \tilde{F}(j, j, du) \text{ is spread out} \\ 3) \forall i \in \mathcal{M}, \forall j \in \mathcal{P}, \tilde{Q}^*(i, j, r) < +\infty \end{cases}$$

REMARK 5.1. Since the process  $(Z_t)_{t \geq 0}$  is irreducible on  $\mathcal{M}$ , for all  $j$  in  $\mathcal{M}$  there exists a path  $i_1, i_2, \dots, i_k$  in  $\mathcal{M}$  such that the process starting from  $j$  returns to  $j$  by this path with a strictly positive probability. If at least one of the probability laws  $Q(i_{l-1}, i_l, du)$  ( $1 \leq l \leq k + 1, i_0 = j, i_{k+1} = j$ ) has a density with respect to the Lebesgue measure then the measure  $\tilde{F}(j, j, du)$  is spread out. Then condition 2) in assumption  $(A_0)$  is satisfied.

REMARK 5.2. Suppose that  $Q(i, j, du)$  is equal to  $P(i, j)f(i, du)$  for any  $i$  and  $j$  in  $E$ . We know that  $Q^*(i, j, r)$  is finite for any  $i$  and  $j$  in  $\mathcal{M}$  (remark 4.3), consequently  $f^*(i, r)$  is finite. In this case, condition 3) is always true.

PROPOSITION 5.3. Under assumption  $(A_0)$ , for any  $i$  and  $j$  in  $\mathcal{M}$  we have:

$$\lim_{t \rightarrow \infty} e^{-rt} \mathbb{P}(Z_t = j / Z_0 = i) = \frac{h^*(j, r) \tilde{F}^*(i, j, r)}{-(\tilde{F}^*)'(j, j, r)}$$

*Proof.* We have:

$$\mathbb{P}(Z_t = j / Z_0 = i) = \int_0^t h(j, t - s) \tilde{R}(i, j, ds).$$

We want to apply proposition 4.11 with  $g(\cdot) = h(j, \cdot)$ . Using the fact that  $r$  is strictly negative (remark 4.8), lemma 4.2 and the assumption  $(A_03)$ , one gets :

$$\begin{aligned} e^{-ru} h(j, u) &\leq \int_{]u, +\infty[} e^{-rs} f(j, ds) = \int_{]u, +\infty[} e^{-rs} \sum_{k \in E} Q(j, k, ds) \\ &\leq \sum_{k \in E} Q^*(j, k, r) = f^*(j, r) < +\infty. \end{aligned}$$

Thus the function  $u \rightarrow e^{-ru} h(j, u)$  is bounded and tends to 0 as  $u$  tends to  $+\infty$ . The Lebesgue integrability condition of the proposition 4.11 is equivalent to  $h^*(j, r) < +\infty$ , which is true since  $f^*(j, r) < +\infty$ .  $\square$

Then under assumption  $(A_0)$ , if the process is not  $r$ -positive, we have for any  $i, j$  in  $\mathcal{M}$ :

$$\lim_{t \rightarrow \infty} e^{-rt} \mathbb{P}(Z_t = j / Z_0 = i) = 0$$

A direct application of proposition 4.13 implies that if the process is not  $r$ -recurrent we obtain the same limit. Then the limit is strictly positive only in the  $r$ -positive case.

PROPOSITION 5.4. Under assumption  $(A_0)$ , the process is  $r$ -positive.

*Proof.* For  $i$  and  $j$  in  $\mathcal{M}$ , let  $\varphi_{i,j}(t) = e^{-rt} \mathbb{P}(Z_t = j / Z_0 = i)$ .

If the process is not  $r$ -positive we have for  $i, j$  in  $\mathcal{M}$ :

$$\lim_{t \rightarrow \infty} \varphi_{i,j}(t) = 0$$

and hence

$$\lim_{u \searrow 0} u \varphi_{i,j}^*(u) = 0 \quad (\varphi_{i,j}^* \text{ Laplace transform of } \varphi_{i,j}).$$

Using  $\lim_{u \searrow 0} u \varphi_{i,j}^*(u) = \lim_{s \searrow r} (s - r) \tilde{P}^*(i, j, s)$  and proposition 3.4, we obtain:

$$\lim_{s \searrow r} (s - r)(sI_1 - A_1(s))^{-1}(i, j) = 0.$$

Since  $r$  is a simple eigenvalue of  $A_1(r)$  by proposition 4.10, and since  $s \rightarrow A_1(s)$  is continuous, in a neighbourhood of  $r$  there exists a simple eigenvalue  $\lambda(s)$  of  $A_1(s)$  such that:  $\lim_{s \searrow r} \lambda(s) = r$ .

We can triangularise the matrix  $A_1(s)$  as  $A_1(s) = \Pi(s)T(s)\Pi^{-1}(s)$  and then  $(sI_1 - A_1(s))^{-1} = \Pi(s)(sI_1 - T(s))^{-1}\Pi^{-1}(s)$ . The matrix  $T(s)$  is lower triangular ; we can suppose that its element  $T(s)(1, 1)$  is equal to  $\lambda(s)$  and the other elements of its first column are equal to 0. The first column of the matrix  $\Pi(s)$  is equal to a right eigenvector  $U(s)$  of  $A_1(s)$  associated with  $\lambda(s)$ . The first row of  $\Pi^{-1}(s)$  is equal to a left eigenvector  $V(s)$  of  $A_1(s)$  associated with  $\lambda(s)$ . The element  $(sI_1 - T(s))^{-1}(1, 1)$  is equal to  $\frac{1}{s - \lambda(s)}$ , and we then get:

$$\lim_{s \searrow r} (s - r)(sI_1 - T(s))^{-1}(1, 1) = 1.$$

For  $(i, j) \neq (1, 1)$ ,  $(sI_1 - T(s))^{-1}(i, j)$  satisfy the following:

$$\frac{K(i, j)(s - \lambda(s))}{\prod_i (s - T(s)(i, i))} = \frac{K(i, j)}{\prod_{i \neq 1} (s - T(s)(i, i))}.$$

Then for  $(i, j) \neq (1, 1)$  we get:

$$\lim_{s \searrow r} (s - r)(sI_1 - T(s))^{-1}(i, j) = 0.$$

On the other hand we have

$$\lim_{s \searrow r} (s - r)(sI_1 - A_1(s))^{-1}(i, j) = U(r, i)V(r, j).$$

But the quantity  $U(r, i)V(r, j)$  is non null for any  $i$  and  $j$ . So there is a contradiction and the process is  $r$ -positive. □

PROPOSITION 5.5. *Under assumption  $(A_0)$ , for any  $i$  and  $j$  in  $\mathcal{M}$  we have:*

$$\lim_{t \rightarrow \infty} \frac{\mathbb{P}(Z_t = j / Z_0 = i)}{\sum_{j \in \mathcal{M}} \mathbb{P}(Z_t = j / Z_0 = i)} = \frac{B(i, j)}{\sum_{j \in \mathcal{M}} B(i, j)}$$

with

$$0 < B(i, j) = \frac{h^*(j, r)\tilde{F}^*(i, j, r)}{-(\tilde{F}^*)'(j, j, r)} < +\infty$$

*Proof.* This is a direct application of proposition 5.3 and proposition 5.4. □

We want to understand the structure of the matrix  $B(i, j)$  on  $\mathcal{M} \times \mathcal{M}$ .

PROPOSITION 5.6. *Under assumption  $(A_0)$ , for any  $i$  in  $\mathcal{M}$ , the vector  $(B(i, j), j \in \mathcal{M})$  is a left eigenvector of the matrix  $A_1(r)$  associated with the eigenvalue  $r$  and for any  $j$  in  $\mathcal{M}$ , the vector  $(B(i, j), i \in \mathcal{M})$  is a right eigenvector of the matrix  $A_1(r)$  associated with the eigenvalue  $r$ .*

*Proof.* Using lemma 4.2, we get for  $l$  and  $j$  in  $\mathcal{M}$ :

$$\begin{aligned} \sum_{i \in \mathcal{M}} B(l, i) A_1(i, j, r) &= \sum_{\{i \in \mathcal{M}/i \neq j\}} \frac{h^*(i, r) \tilde{F}^*(l, i, r) Q^*(i, j, r)}{-(\tilde{F}^*)'(i, i, r) h^*(i, r)} \\ &\quad - \sum_{\{i \in E/i \neq j\}} \frac{Q^*(j, i, r) h^*(j, r) \tilde{F}^*(l, j, r)}{h^*(j, r) - (\tilde{F}^*)'(j, j, r)} \\ &= \frac{\tilde{F}^*(l, j, r)}{-(\tilde{F}^*)'(j, j, r)} (1 - f^*(j, r)) \\ &= \frac{\tilde{F}^*(l, j, r)}{-(\tilde{F}^*)'(j, j, r)} r h^*(j, r) \\ &= r B(l, j). \end{aligned}$$

In the same way we get:

$$\begin{aligned} \sum_{i \in \mathcal{M}} A_1(l, i, r) B(i, j) &= \sum_{\{i \in \mathcal{M}/i \neq l\}} \frac{Q^*(l, i, r) h^*(j, r) \tilde{F}^*(i, j, r)}{-h^*(l, r) (\tilde{F}^*)'(j, j, r)} \\ &\quad - \sum_{\{i \in E/i \neq l\}} \frac{Q^*(l, i, r) h^*(j, r) \tilde{F}^*(l, j, r)}{h^*(l, r) - (\tilde{F}^*)'(j, j, r)} \\ &= \frac{h^*(j, r)}{-h^*(l, r) (\tilde{F}^*)'(j, j, r)} \tilde{F}^*(l, j, r) (1 - f^*(l, r)) \\ &= r B(l, j). \end{aligned}$$

□

We have seen that  $r$  is the Perron-Frobenius eigenvalue of  $A_1(r)$  and we know that the eigenvector is unique up to scalar multiples. If  $V$  and  $W$  are left and right eigenvectors, we can immediately deduce that:  $B(i, j) = CW(i)V(j)$ . We then obtain the following theorem.

**THEOREM 5.7.** *Under assumption  $(A_0)$ , for any  $i$  and  $j$  in  $\mathcal{M}$ :*

$$\lim_{t \rightarrow \infty} \frac{\mathbb{P}(Z_t = j / Z_0 = i)}{\sum_{j \in \mathcal{M}} \mathbb{P}(Z_t = j / Z_0 = i)} = \frac{V(j)}{\sum_{j \in \mathcal{M}} V(j)}$$

where  $V$  is a left eigenvector of  $A_1(r)$  associated with  $r$ .

### 6. FAILURE RATE

An important quantity in reliability studies is the failure rate and especially the asymptotic failure rate.

**DEFINITION 6.1.** For any state  $k$  and any time  $t$ , let  $\lambda(k, t)$  be the failure rate of the system defined by :

$$\lambda(k, t) = \lim_{\delta \searrow 0} \frac{1}{\delta} \mathbb{P}(Z_{t+\delta} \in \mathcal{P} / Z_t \in \mathcal{M}, Z_0 = k)$$

when this limit exists.

We can also write:

$$\lambda(k, t) = \frac{1}{\sum_{i \in \mathcal{M}} \mathbb{P}(Z_t = i / Z_0 = k)} \sum_{i \in \mathcal{M}} \sum_{j \in \mathcal{P}} \lim_{\delta \searrow 0} \frac{1}{\delta} \mathbb{P}(Z_{t+\delta} = j, Z_t = i / Z_0 = k)$$

In this section, we suppose that the following assumptions are satisfied:

$$(A_1) : \begin{cases} 1) \text{ assumption } (A_0) \\ 2) \forall i \in \mathcal{M}, \forall j \in \mathcal{P}, Q(i, j, du) = q(i, j, u) du \\ 3) \forall i \in \mathcal{M}, \forall j \in \mathcal{P}, u \rightarrow q(i, j, u) \text{ is continuous a.e.} \\ 4) \forall i \in \mathcal{M}, \forall j \in \mathcal{P}, u \rightarrow q(i, j, u) \text{ is bounded} \\ 5) \forall i \in \mathcal{M}, \forall j \in \mathcal{P}, \lim_{u \rightarrow +\infty} e^{-ru} q(i, j, u) = 0 \end{cases}$$

PROPOSITION 6.2. *Under assumption (A<sub>1</sub>), we have for any k in M and t in R<sub>+</sub>:*

$$\lambda(k, t) = \frac{1}{\sum_{i \in \mathcal{M}} \mathbb{P}(Z_t = i / Z_0 = k)} \sum_{i \in \mathcal{M}} \sum_{j \in \mathcal{P}} \int_0^t q(i, j, t - s) \tilde{R}(k, i, ds).$$

*Proof.* For *i* in *M* and *j* in *P* we get:

$$\begin{aligned} \mathbb{P}(Z_{t+\delta} = j, Z_t = i / Z_0 = k) &= \\ &\sum_{n \geq 0} \mathbb{P}(\tilde{T}_n \leq t < \tilde{T}_{n+1} \leq t + \delta < \tilde{T}_{n+2}, \tilde{X}_n = i, \tilde{X}_{n+1} = j / \tilde{X}_0 = k) \\ &+ \sum_{n \geq 0} \sum_{l_1 \in E} \sum_{l_2 \in E} \mathbb{P}(\tilde{T}_n \leq t < \tilde{T}_{n+1} < \tilde{T}_{n+2} < t + \delta, \tilde{X}_n = i, \tilde{X}_{n+1} = l_1, \\ &\tilde{X}_{n+2} = l_2, Z_{t+\delta} = j / \tilde{X}_0 = k). \end{aligned}$$

The last term is less than:

$$\begin{aligned} &\sum_{n \geq 0} \sum_{l_1 \in E} \sum_{l_2 \in E} \int_{\{u_1 \leq t < u_1 + u_2 < u_1 + u_2 + u_3 < t + \delta\}} \tilde{Q}_n(k, i, du_1) \tilde{Q}(i, l_1, du_2) \tilde{Q}(l_1, l_2, du_3) \\ &\leq \sum_{l_1 \in E} \sum_{l_2 \in E} \int_{[0, t]} \tilde{R}(k, i, du_1) \int_{\{t - u_1 < u_2, u_2 + u_3 < t - u_1 + \delta\}} \tilde{Q}(i, l_1, du_2) \tilde{Q}(l_1, l_2, du_3) \\ &\leq o(\delta). \end{aligned}$$

Elsewhere:

$$\begin{aligned} &\sum_{n \geq 0} \mathbb{P}(\tilde{T}_n \leq t < \tilde{T}_{n+1} \leq t + \delta < \tilde{T}_{n+2}, \tilde{X}_n = i, \tilde{X}_{n+1} = j / \tilde{X}_0 = k) \\ &= \sum_{n \geq 0} \int_{(0, t]} \tilde{Q}_n(k, i, ds) \mathbb{P}(\tilde{X}_1 = j, t - s < \tilde{T}_1 \leq t - s + \delta < \tilde{T}_2 / \tilde{X}_0 = i) \\ &= \sum_{n \geq 0} \int_{[0, t]} \tilde{Q}_n(k, i, ds) \int_{[t-s, t-s+\delta]} \tilde{Q}(i, j, du_1) \sum_l \int_{\{t-s+\delta < u_1 + u_2\}} \tilde{Q}(j, l, du_2) \\ &= \sum_l \int_{[0, t]} \tilde{R}(k, i, ds) \int \tilde{Q}(j, l, du_2) \int_{\{t-s < u_1 \leq t-s+\delta < u_1 + u_2\}} q(i, j, u_1) du_1. \end{aligned}$$

Since *q(i, j, u)* is a.e. continuous, we have

$$\begin{aligned} &\lim_{\delta \rightarrow 0} \frac{1}{\delta} \int 1_{\{t-s < u_1 \leq t-s+\delta < u_1 + u_2\}} q(i, j, u_1) du_1 \\ &= \lim_{\delta \rightarrow 0} \frac{1}{\delta} \int 1_{\{t-s < u_1 \leq t-s+\delta\}} q(i, j, u_1) du_1 \\ &= q(i, j, t - s) \text{ a.s.} \end{aligned}$$

We can conclude with the dominated convergence theorem. □

We want to identify the asymptotic failure rate, that is the limit, if it exists, of  $\lambda(k, t)$  when  $t$  tends to  $+\infty$ .

**THEOREM 6.3.** *Under assumption  $(A_1)$ , we have:*

$$\lim_{t \rightarrow \infty} \lambda(k, t) = |r|.$$

*Proof.* The conditions of theorem 5.7 are fulfilled and we know that:

$$\lim_{t \rightarrow \infty} e^{-rt} \mathbb{P}(Z_t = i / Z_0 = k) = CW(k)V(i).$$

Now apply proposition 4.11 with the function  $g$  equal to the function  $u \rightarrow q(i, j, u)$  with  $i$  in  $\mathcal{M}$  and  $j$  in  $\mathcal{P}$ . We then obtain for  $k$  in  $\mathcal{M}$ :

$$\begin{aligned} \lim_{t \rightarrow \infty} e^{-rt} \int_0^t q(i, j, t-s) \tilde{R}(k, i, ds) &= \frac{q^*(i, j, r) \tilde{F}^*(k, i, r)}{-(\tilde{F}^*)'(i, i, r)} \\ &= CW(k)V(i)A(i, j, r) \text{ for } i \neq j. \end{aligned}$$

and

$$\begin{aligned} \lim_{t \rightarrow \infty} \lambda(k, t) &= \frac{1}{\sum_{i \in \mathcal{M}} CW(k)V(i)} \sum_{i \in \mathcal{M}} \sum_{j \in \mathcal{P}} CW(k)V(i)A(i, j, r) \\ &= \frac{1}{\sum_{i \in \mathcal{M}} V(i)} \sum_{i \in \mathcal{M}} V(i) \left( \sum_{j \in \mathcal{P}} A(i, j, r) \right) \\ &= -\frac{1}{\sum_{i \in \mathcal{M}} V(i)} \sum_{i \in \mathcal{M}} V(i) \left( \sum_{j \in \mathcal{M}} A(i, j, r) \right) \\ &= -\frac{1}{\sum_{i \in \mathcal{M}} V(i)} \sum_{j \in \mathcal{M}} rV(j) \\ &= |r|. \end{aligned}$$

□

So we find for the semi-Markov process that the same result as for the Markov process holds.

## 7. A NUMERICAL EXAMPLE: A TWO-UNIT PARALLEL SYSTEM WITH SEQUENTIAL PREVENTIVE MAINTENANCE

### 7.1. THE RELIABILITY MODEL

A semi-Markov reliability model of a two-unit parallel system with sequential preventive maintenance (PM) will now be considered. This model has been used as an example in Alam (1984) and Csenki (1995).

The system consists of two units, A and B. The model has nine states. The states and the transitions are shown in Fig. 1.

Preventive maintenance is carried out off-line on A and B alternately. The unit which is due for PM is removed from the system after  $c$  hours of parallel service and returned to service after a random time of maintenance. Thus, until failure occurs, states 1, 2, 3 and 4 are visited in this order. In states 1 and 3 the units A and B are up. In state 2 unit A is under preventive maintenance and unit B is up. In state 4 unit A is up and unit B is under preventive maintenance. This implies that from state 1 the next PM is on unit A and not B. The process makes a transition from state 1

to state 6 if unit B fails during a sojourn in state 1. In state 6, unit A is in service while unit B undergoes repair. There are two possible transitions from state 6. If unit A fails before B's repair is completed, system failure ensues by transition to state 9 where the two units are down. The other possible move from state 6 is back to state 1 which happens if A remains in service throughout B's repair. From state 1, the only transition hitherto not considered is that of state 5 which occurs if unit A fails within the projected  $c$  hours of parallel service with unit B still being in the up state. Since it is assumed that completed repair includes PM, the system enters state 3 (the next projected PM is on unit B) upon successful completion of the repair on A in state 5. State 8 can be entered from state 2 only. This happens if unit B fails while unit A is under PM. The system then resides in state 8, after which unit A enters service and repair is started on unit B (state 6).

PM : preventive maintenance

Fig. 1

Departure from state 9 happens as soon as the repair on any one of the two units is completed. The remaining aspects of the system are obtained by interchanging the roles of A and B. In this sense, 3, 4, 5 and 7 correspond to 1, 2, 6 and 8. We assume that all the random variables corresponding

to failure, repair or maintenance times are independent. The set of 'system up' states is 1, 2, 3, 4, 5, 6 and the set of 'system down' states is 7, 8, 9.

The constant failure rates of A and B are  $\lambda_A$  and  $\lambda_B$  respectively. The constant repair rates are  $\mu_A$  and  $\mu_B$  respectively. We assume that the duration of maintenance has a Gamma probability distribution with parameters  $\alpha$  and  $\beta$ .

In the following we are only interested in the transition from the 'system up' states, so the parameters for our computations are  $\lambda_A, \lambda_B, \mu_A, \mu_B, c, \alpha$  and  $\beta$ .

7.2. COMPUTATION OF THE CHARACTERISTICS OF THE MODEL

The transition laws  $Q(i, j, du)$  of the semi-Markov model are:

$$\begin{aligned}
 Q(1, 2, du) &= \exp(-(\lambda_A + \lambda_B)c) \delta_c(u) \\
 Q(1, 5, du) &= \lambda_A \exp(-(\lambda_A + \lambda_B)u) 1_{(u \leq c)} du \\
 Q(1, 6, du) &= \lambda_B \exp(-(\lambda_A + \lambda_B)u) 1_{(u \leq c)} du \\
 Q(2, 3, du) &= \frac{\beta^\alpha}{\Gamma(\alpha)} u^{\alpha-1} \exp(-(\beta + \lambda_B)u) du \\
 Q(2, 8, du) &= \lambda_B \exp(-\lambda_B u) \left( \int_u^\infty \frac{\beta^\alpha}{\Gamma(\alpha)} t^{\alpha-1} e^{-\beta t} dt \right) du \\
 Q(3, 4, du) &= \exp(-(\lambda_A + \lambda_B)c) \delta_c(u) \\
 Q(3, 5, du) &= \lambda_A \exp(-(\lambda_A + \lambda_B)u) 1_{(u \leq c)} du \\
 Q(3, 6, du) &= \lambda_B \exp(-(\lambda_A + \lambda_B)u) 1_{(u \leq c)} du \\
 Q(4, 1, du) &= \frac{\beta^\alpha}{\Gamma(\alpha)} u^{\alpha-1} \exp(-(\beta + \lambda_A)u) du \\
 Q(4, 7, du) &= \lambda_A \exp(-\lambda_A u) \left( \int_u^\infty \frac{\beta^\alpha}{\Gamma(\alpha)} t^{\alpha-1} e^{-\beta t} dt \right) du \\
 Q(5, 3, du) &= \mu_A \exp(-(\mu_A + \lambda_B)u) du \\
 Q(5, 9, du) &= \lambda_B \exp(-(\mu_A + \lambda_B)u) du \\
 Q(6, 1, du) &= \mu_B \exp(-(\mu_B + \lambda_A)u) du \\
 Q(6, 9, du) &= \lambda_A \exp(-(\mu_B + \lambda_A)u) du
 \end{aligned}$$

It is easy to verify that the process  $(Z_t)_{t \geq 0}$  is irreducible on  $\mathcal{M} = \{1, 2, 3, 4, 5, 6\}$  and that for all  $j$  in  $\mathcal{M}$  the measure  $\tilde{F}(j, j, du)$  is spread out (cf remark 5.1).

The matrix  $\tilde{Q}_1^*(s)$  of the Laplace transforms is equal to:

$$\begin{pmatrix}
 0 & e^{-(\lambda_A + \lambda_B + s)c} & 0 & 0 & \frac{\lambda_A F(s)}{\lambda_A + \lambda_B + s} & \frac{\lambda_B F(s)}{\lambda_A + \lambda_B + s} \\
 0 & 0 & \frac{\beta^\alpha}{(\beta + \lambda_B + s)^\alpha} & 0 & 0 & 0 \\
 0 & 0 & 0 & e^{-(\lambda_A + \lambda_B + s)c} & \frac{\lambda_A F(s)}{\lambda_A + \lambda_B + s} & \frac{\lambda_B F(s)}{\lambda_A + \lambda_B + s} \\
 \frac{\lambda^\alpha}{(\beta + \lambda_A + s)^\alpha} & 0 & 0 & 0 & 0 & 0 \\
 0 & 0 & \frac{\mu_A}{\mu_A + \lambda_B + s} & 0 & 0 & 0 \\
 \frac{\mu_B}{\mu_B + \lambda_A + s} & 0 & 0 & 0 & 0 & 0
 \end{pmatrix}$$

with  $F(s) = 1 - e^{-(\lambda_A + \lambda_B + s)c}$ .

The quantity  $\tilde{r}$  is equal to  $\max(-(\lambda_A + \lambda_B), -(\beta + \lambda_A), -(\beta + \lambda_B), -(\mu_A + \lambda_B), -(\mu_B + \lambda_A))$ . Since the Perron-Frobenius  $\rho(s)$  of  $\tilde{Q}_1^*(s)$  tends to  $+\infty$  as  $s$  decreases towards  $\tilde{r}$ , the convergence parameter  $r$  satisfies  $\rho(r) = 1$ . Then (cf remark 4.7) the process is  $r$ -recurrent. Since  $r > \tilde{r}$ , it is easy to verify that for all  $i$  in  $\mathcal{M}$  and  $j$  in  $\mathcal{P}$ ,  $\tilde{Q}^*(i, j, r)$  is finite. Then assumption  $(A_0)$  is satisfied. Assumption  $(A_1)$  is also satisfied since all the transitions from

$i$  in  $\mathcal{M}$  to  $j$  in  $\mathcal{P}$  are governed by probability distributions which have the required properties. We can then use the preceding results.

The matrix  $A_1(s)$  is equal to:

$$\begin{pmatrix} -(\lambda_A + \lambda_B + G(s)) & G(s) & 0 & 0 & \lambda_A & \lambda_B \\ 0 & -(\lambda_B + H_B(s)) & H_B(s) & 0 & 0 & 0 \\ 0 & 0 & -(\lambda_A + \lambda_B + G(s)) & G(s) & \lambda_A & \lambda_B \\ H_A(s) & 0 & 0 & -(\lambda_A + H_A(s)) & 0 & 0 \\ 0 & 0 & \mu_A & 0 & -(\mu_A + \lambda_B) & 0 \\ \mu_B & 0 & 0 & 0 & 0 & -(\mu_B + \lambda_A) \end{pmatrix}$$

with  $G(s) = \frac{(\lambda_A + \lambda_B + s) \exp(-(\lambda_A + \lambda_B + s)c)}{1 - \exp(-(\lambda_A + \lambda_B + s)c)}$ ,  $H_A(s) = \frac{(\lambda_A + s)\beta^\alpha}{(\beta + \lambda_A + s)^\alpha - \beta^\alpha}$  and  $H_B(s) = \frac{(\lambda_B + s)\beta^\alpha}{(\beta + \lambda_B + s)^\alpha - \beta^\alpha}$ .

### 7.3. NUMERICAL RESULTS

As a computational example we take the following values, with the hour as a unit of time:

$\lambda_A$	$\lambda_B$	$\mu_A$	$\mu_B$	$c$	$\alpha$	$\beta$
0.01	0.01	0.1	0.1	40	400	0.05

Coefficients  $\alpha$  and  $\beta$  are chosen so that the mean value and the standard deviation of the  $\Gamma$  distribution with parameters  $\alpha$  and  $\beta$  are respectively equal to 20 and 1.

In order to compute the convergence parameter  $r$ , we solve the equation:  $\rho(s) = 1$  where  $\rho(s)$  is the biggest eigenvalue of  $\tilde{Q}_1^*(s)$  (cf remark 3.3). This computation gives the value  $r = -0.0034$ . Then the asymptotic failure rate of the system is equal to (cf theorem 6.3):

$ r  = 0.0034$
----------------

Then we compute  $MTTF(i) = -\sum_{j \in \mathcal{M}} (A_1(0))^{-1}(i, j)$ :

$MTTF(i)$ :	309.4	271.4	309.4	271.4	290.4	290.4
-------------	-------	-------	-------	-------	-------	-------

The quasi-stationary distribution is equal to the normalized left eigenvector  $V$  of  $A_1(r)$  associated with the eigenvalue  $r$  (cf theorem 5.7):

$V(i)$ :	0.33	0.11	0.33	0.11	0.06	0.06
----------	------	------	------	------	------	------

These computations have been carried out using MATLAB on a workstation. They take a few seconds.
